The goal of this quality assurance project was to analyze the clinical applications of two outcome tools, the FEW and the QUEST 2.0. The data for the project was collected from the medical records of the Center for Assistive Technology (CAT) at the University of Pittsburgh Medical Center (UPMC). The aim of the project was to determine: (1) if there were any changes in the functioning of the clients, (2) if there were any correlations between the FEW and the QUEST data, (3) and, if the time it took to deliver the MAE is related to the level of the clients' satisfaction. The results indicate that the intervention has been effective in improving the function of the clients. There was no relationship observed between the clients' functioning and their satisfaction. There was also no relationship observed between the time it takes to deliver the wheelchair and the satisfaction of the clients.
